ELECTRONICS CORPORATION

9  
9  
9  
N  
B

A vertical column of large, bold, black numbers and letters. From top to bottom, it contains four "9"s, followed by "N", and then "B". The "9"s are arranged in a staggered pattern where each subsequent "9" is positioned to the right of the previous one. The "N" and "B" are also positioned to the right of the "9"s.

*Service Manual*

# Safety Summary

## 1. POWER UP WARNING —

This product uses a switch mode power supply to provide the monitor chassis with isolation from the AC line. Although servicing the secondary circuitry can be safely done without the use of an AC isolation transformer, **it is recommended that an isolation transformer be used when servicing this product.** This will prevent shock hazard in the event of accidental or erroneous contact with primary power supply circuitry. Before servicing is performed, read all the precautions labelled on the CRT chassis.

## 2. X-RAY RADIATION WARNING NOTICE

**WARNING:** PARTS WHICH INFLUENCE X-RAY RADIATION IN HORIZONTAL DEFLECTION, HIGH VOLTAGE CIRCUITS, PICTURE TUBE, ETC. ARE INDICATED BY ★ ON THE SCHEMATIC DIAGRAM. FOR REPLACEMENT, USE ONLY THE TYPE SHOWN IN THE PARTS LIST.

## 3. HIGH VOLTAGE —

This monitor contains HIGH VOLTAGES derived from power supplies delivering LETHAL quantities of energy. Do not attempt to service until all precautions necessary for working on HIGH VOLTAGE equipment have been observed.

## 4. CRT HANDLING —

Care must be taken not to bump or scratch the picture tube as this may cause the picture tube to implode resulting in personal injury. Shatter proof goggles must be worn when handling the CRT. **HIGH VOLTAGE CHARGE REMAINS PRESENT ON THE CRT ANODE AFTER THE SET IS POWERED DOWN. THE CRT ANODE MUST BE DISCHARGED TO CHASSIS GROUND BEFORE HANDLING CRT.** Do not handle the CRT by the neck.

## 5. PRODUCT SAFETY NOTICE

**WARNING:** FOR CONTINUED SAFETY, REPLACE SAFETY CRITICAL COMPONENTS WITH MANUFACTURER RECOMMENDED PARTS. THESE PARTS ARE IDENTIFIED BY △ ON THE SCHEMATIC DIAGRAM.

**AVERTISSEMENT:** POUR MAINTENIR LE DEGRE DE SECURITE DE L'APPAREIL NE REMPLACER LES COMPSANTS DONT LE FONCTIONNEMENT EST CRITIQUE POUR LA SECURITE QUE PAR LE FABRICANT.

For replacement purposes, use the same type or specified type of wire and cable, assuring the positioning of the wires is followed (especially for High Voltage and power supply circuits). Use of alternative wiring or positioning could result in damage to the moniotr, shock or fire.

# Theory of Operation

## SWITCHMODE POWER SUPPLY

AC power is converted to DC by a bridge rectifier consisting of D101, D102, D103 and D104, and by filter capacitor C105. Start up voltage for U101 is supplied through R102 and R103. U101 oscillator frequency is determined by values of R116 and C116. Pin 6 of U101 provides a square wave output to drive switching MOSFET Q101. Switching action of Q101 generates a square wave using primary of T101 as load. A network consisting of C106, R104 and D107 acts as a snubber to prevent voltage spikes generated during switching from reaching levels that could damage Q101. Power is transferred to the secondary windings through the transformer action of T101. Voltages from the secondary windings are rectified and filtered providing output voltages to supply monitor.

Voltage regulation is achieved by sensing the output voltage of a tertiary winding on T101. The voltage on this winding is rectified and filtered (D112 and C100) and fed to pin 2 of U101 through a divider network. This sense voltage varies in proportion to the output voltage and is used to change the duty cycle of the square wave drive to Q101 in order to correct changes in output voltage. The waveform from the tertiary winding is also fed through D113 and C118 to generate the DC supply voltage for U101.

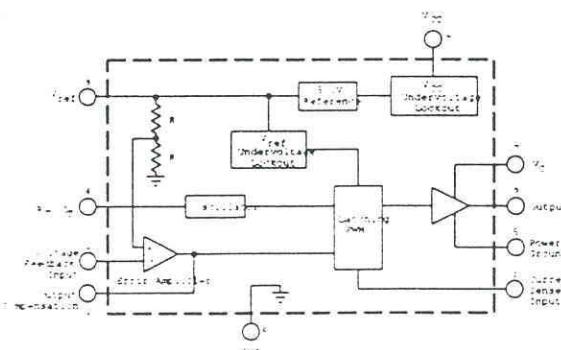

Current foldback is used to protect the supply from excessive load current. The current through Q101 is sensed at R108 and a proportional voltage is fed into pin 3 of Q101. If the voltage at pin 3 exceeds 0.6VDC, U101 shuts off the output at pin 6. U101 will periodically try to restart, however if the load fault is still present, the supply will continue to go into the shutdown mode. This condition will cause the supply to produce a slight ticking sound.

## SYNC DECODER OPERATION

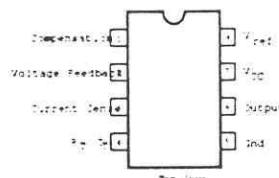

Vertical sync is fed into a pair of XOR gate (pins 9 and 12 of U302). This circuit configuration will provide a negative sync output at pin 8 for the vertical processor regardless of the polarity of the input signal. In addition, the output at pin 11 will be at a high or low logic level depending on the polarity of the vertical sync signal. This logic signal is fed to pin 3 of decoder IC U301.

Horizontal sync is fed into pin 5 of a second pair of XOR gates (pin 2 and 5 or U302) and is processed in a manner similar to the vertical sync signal. The negative horizontal sync output is provided at pin 6 and the DC logic signal for the decoder IC is provided at pin 3. In addition, the negative horizontal sync is fed to the frequency sensing circuit consisting of U303A and B.

CURRENT MODE CONTROLLER

PIN CONNECTIONS

# Theory of Operation

(continued)

The frequency sensing circuit detects whether a 31.5kHz (VGA) or 35.1kHz (SVGA) signal is present. Pin 5 is high for a 31.5 kHz signal (modes 1, 2 and 3) and low for a 35.1 kHz signal (mode 4). This logic signal is inverted by Q301 and fed to U301, Q302 and Q303.

For VGA modes 1,2 and 3, decoder IC U301 will pull down pin 4,5 or 6, selecting R319, R320 or R321 to set the vertical size for the detected mode. For the 35.1kHz SVGA mode, the outputs of U301 remain floating (high) and Q301 turns on, causing the vertical size to be set by VR318. In addition, Q302 turns on which turns on Q706 causing R746 to become part of the horizontal oscillator RC circuit (in parallel with R710 and VR701). This causes the horizontal oscillator frequency to increase to 35.1kHz.

## VERTICAL CIRCUIT

Vertical sync from the decoder circuit is AC coupled through C304 to the vertical processor (U600). The vertical oscillator frequency is determined by the values of VR600, R609 and C603. The output from the oscillator is fed to a ramp generator. Linearity correction is accomplished by shaping the ramp through an external RC network connected between pins 1 and 12. The ramp is amplified and the output taken from pin 4 is buffered by Q601 and Q602 before it reaches the yoke.

The yoke is AC coupled through C612. The yoke current is sensed at R621 where a proportional voltage is fed back to the internal amplifier at pin 10.

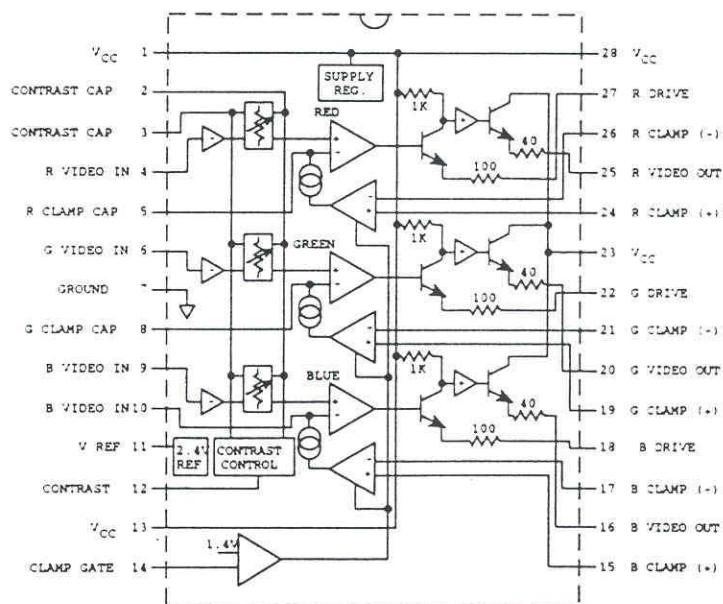

U600 uses a pump-up circuit to reduce retrace time. During retrace the voltage at pin 3 is increased to approximately 20 volts. Emitter follower Q600 then boosts the collector voltage of Q601 to approximately 44 volts using the charge stored C604. The output at pin 4 is also increased, and the resulting increased voltage across the yoke decreases the retrace time.

## HORIZONTAL CIRCUIT

Horizontal sync from the decoder circuit is applied to pin 1 of U700. The first section of U700 is an adjustable delay, the delay being determined by the values of C701, R706 and VR700. Adjusting VR700 will move the position of the video on the screen horizontally. The output of the delay circuit is fed to the phase detector which compares the frequency of the sync signal to the frequency of the horizontal oscillator and produces a DC correction voltage to keep the oscillator frequency locked to the incoming sync frequency. The DC correction voltage is fed through R708 to the oscillator. The free running frequency of the oscillator is set by VR701.

## U200

LM1203 RGB VIDEO AMPLIFIER SYSTEM

# Theory of Operation

(continued)

## HIGH VOLTAGE SHUTDOWN CIRCUIT

The flyback pulse is sensed from the filament winding (pin 9) of the flyback transformer. The pulse is converted to a DC level proportional to the high voltage by D710 and C729. VR702 is adjusted so that when the high voltage exceeds an acceptable level, the internal X-Ray protect circuit of U700 (pin 13) will turn off the horizontal oscillator causing the high voltage to drop to zero. This circuit acts as a latch, therefore power to the monitor must be turned off for a few seconds in order to reset this circuit after it has been tripped.

## VIDEO CIRCUIT

Red, green and blue video signals are applied to pins 10, 9 and 8 of P301 and are AC coupled to video processor IC U200. DC bias for the input amplifiers is provided from the output of pin 11 through R206, R207 and R250. The gain (contrast) of the RGB amplifiers is controlled simultaneously by the DC voltage applied at pin 12, which varies with the setting of the contrast control VR201.

DC restoration occurs during retrace when the input signal is at black level. A negative pulse derived from horizontal sync amplifier Q205 is applied to the clamp gate input at pin 14. During this pulse, the black level of the signal is clamped to a DC level which is determined by the setting of brightness control VR200.

RGB output signals from 200 are fed through buffer amplifiers Q200, Q201 and Q202 to the neckboard cascode video amplifiers. The outputs of these amplifiers are fed to the CRT cathodes.

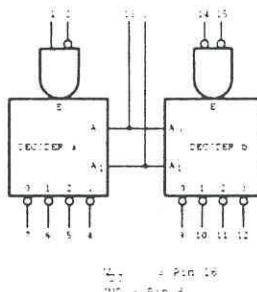

Blanking is provided by pulling down the video signals to below black level during the horizontal and vertical blanking periods. This is accomplished by turning on Q204 (vertical) or Q208 (horizontal), turning on diodes D209, D210 and D211, forcing the video outputs low. The horizontal blanking signal is derived from the filament pulse, and the vertical blanking signal is derived from the vertical retrace pulse.

Beam limiting is provided by sensing the voltage developed across R801. When beam current reaches approximately 800uA, Q800 begins to turn on and Q801 begins to turn off. As Q801 turns off, the voltage applied to the CRT grid 1 begins to go negative, causing the beam current to limit.
